

Problem Set 4

Drohanash Majumdar, 704

2026-02-16

Problem to demonstrate the utility of nonlinear regression over linear regression.

Get the fgl data set from “MASS” library.

```
df1 = fgl
head(df1)

##      RI     Na    Mg    Al    Si    K    Ca   Ba    Fe type
## 1  3.01 13.64 4.49 1.10 71.78 0.06 8.75  0 0.00 WinF

## 6 -2.04 12.79 3.61 1.62 72.97 0.64 8.07  0 0.26 WinF
```

(a) Considering the refractive index (RI) of “Vehicle Window glass” as the variable of interest and assuming linearity of regression, run multiple linear regression of RI on different metallic oxides. From the p value, report which metallic oxide best explains the refractive index.

```
df1_subset = subset(df1, type == "Veh")
model = lm(RI ~ Na + Mg + Al + Si + K + Ca + Ba + Fe, data = df1_subset)
summary(model)

##
## Call:
## lm(formula = RI ~ Na + Mg + Al + Si + K + Ca + Ba + Fe, data = df1_subset)
##

Note: * p<0.1; ** p<0.05; *** p<0.01

(c) Can you further improve the regression of the refractive index of “Vehicle Window glass” on the predictor chosen by you in part (a)? Give the new fitted model and compare its performance with the model in (b).

```
fit_quad = lm(RI ~ Fe + I(Fe^2), data = df1_subset) #adding a quadratic term

summary(fit_quad)

##
## Call:
## lm(formula = RI ~ Fe + I(Fe^2), data = df1_subset)
##
## Residuals:
##      Min    1Q   Median    3Q    Max 
## -1.6215 -1.1715 -0.1345  0.5985  3.5485 
##
## Coefficients:
##             Estimate Std. Error t value Pr(>|t|)    
## (Intercept) -0.2785    0.4712  -0.591   0.564    
## Fe          -12.1810   12.0408  -1.012   0.329    
## I(Fe^2)      65.9600   37.0798   1.779   0.097 .  
## ---        
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 1.645 on 14 degrees of freedom
```

```
## Multiple R-squared:  0.3554, Adjusted R-squared:  0.2633
## F-statistic:  3.86 on 2 and 14 DF,  p-value: 0.04623
```

Comparison :

```
cat("R^2 value for simple model : ",summary(fit_simple)$r.squared)
## R^2 value for simple model :  0.2097192
cat("R^2 value for quadratic model : ",summary(fit_quad)$r.squared)
## R^2 value for quadratic model :  0.355413
```

Conclusion : The quadratic model improves the fit compared to the simple linear model, as indicated by the higher R^2 and lower residual standard error. The overall model becomes statistically significant at the 5% level. However, the individual coefficients are not strongly significant, suggesting only moderate evidence of a nonlinear relationship between RI and Fe.

Problem to demonstrate multicollinearity.

Consider the Credit data in the ISLR library. Choose balance as the response and Age, Limit and Rating as the predictors.

```
df2 = Credit
head(df2)

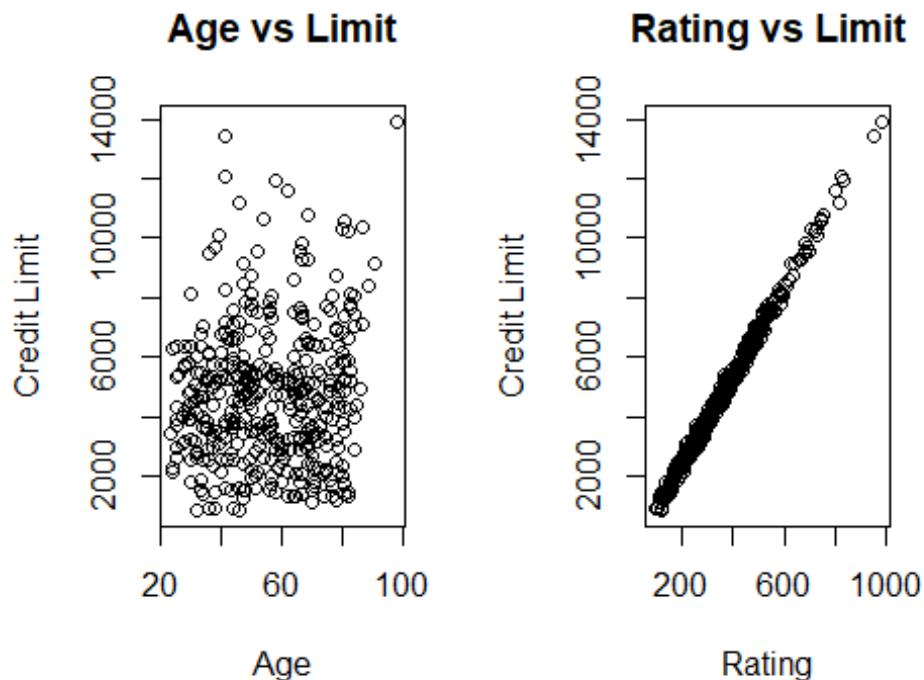

##   ID Income Limit Rating Cards Age Education Gender Student Married
Ethnicity
## 1  1 14.891  3606    283     2  34        11  Male      No    Yes
Caucasian
## 2  2 106.025  6645    483     3  82        15 Female     Yes    Yes
Asian
## 3  3 104.593  7075    514     4  71        11  Male      No    No
Asian
## 4  4 148.924  9504    681     3  36        11 Female     No    No

## 5  5 55.882   4897    357     2  68        16  Male      No    Yes
Caucasian
## 6  6 80.180   8047    569     4  77        10  Male      No    No
Caucasian
##   Balance
## 1      333
## 2      903
## 3      580
## 4      964
## 5      331
## 6     1151
```

(a) Make a scatter plot of (i) Age versus Limit and (ii) Rating Versus Limit. Comment on the scatter plot.

```
par(mfrow = c(1, 2))

plot(df2$Age, df2$Limit, main = "Age vs Limit", xlab = "Age", ylab = "Credit
Limit")

plot(df2$Rating, df2$Limit, main = "Rating vs Limit", xlab = "Rating", ylab =
"Credit Limit")
```

```
par(mfrow = c(1, 1))
```

Comments : (i) Age vs Limit

- Type of relationship: No clear linear relationship
- Direction: No clear direction (neither upward nor downward trend)
- Strength: Very weak

The points are widely scattered without any visible pattern. This suggests that Age does not strongly explain Credit Limit.

(ii) Rating vs Limit

- Type of relationship: Strong linear relationship

- Direction: Positive
- Strength: Very strong

The points lie almost perfectly along a straight upward-sloping line. This indicates that as Rating increases, Limit increases almost proportionally.

(b) Run three separate regressions: (i) Balance on Age and Limit (ii) Balance on Age, Rating and Limit (iii) Balance on Rating and Limit. Present all the regression output in a single table using stargazer. What is the marked difference that you can observe from the output?

```
model21 <- lm(Balance ~ Age + Limit, data = df2)

model22 <- lm(Balance ~ Age + Rating + Limit, data = df2)

model23 <- lm(Balance ~ Rating + Limit, data = df2)

stargazer(model21, model22, model23, type = "html", title = "Regression
Results: Balance as Response", column.labels = c("Age + Limit", "Age + Rating
+ Limit", "Rating + Limit"))
```

Regression Results: Balance as Response

	Dependent variable:		
	Balance		
	Age + Limit (1)	Age + Rating + Limit (2)	Rating + Limit (3)
Age	-2.291*** (0.672)	-2.346*** (0.669)	
Rating		2.310** (0.940)	2.202** (0.952)
Limit	0.173*** (0.005)	0.019 (0.063)	0.025 (0.064)
Constant	-173.411*** (43.828)	-259.518*** (55.882)	-377.537*** (45.254)
Observations	400	400	400
R ²	0.750	0.754	0.746
Adjusted R ²	0.749	0.752	0.745
Residual Std. Error	230.532 (df = 397)	229.080 (df = 396)	232.320 (df = 397)
F Statistic	594.988*** (df = 2; 397)	403.718*** (df = 3; 396)	582.820*** (df = 2; 397)

Note:

*p<0.1; **p<0.05; ***p<0.01

Observations : The key difference:

1. In model (i), Limit is highly significant.
2. In model (iii), Rating is highly significant.
3. But in model (ii) (**both included**) :
 - One of them often becomes insignificant.
 - Standard errors increase.
 - Coefficient signs or magnitudes may shift.

This happens because Rating and Limit are highly correlated. That is multicollinearity.

(c) Calculate the variance inflation factor (VIF) and comment on multicollinearity.

```
vif_values <- vif(model22)
print(vif_values)

##          Age      Rating      Limit
## 1.011385 160.668301 160.592880
```

Comment on multicollinearity : There is severe multicollinearity between Rating and Limit, as indicated by extremely high VIF values (≈ 160). Age shows no multicollinearity. The instability in the regression coefficients when both Rating and Limit are included is due to this strong linear dependence.

Problem to demonstrate the detection of outlier, leverage and influential points.

Attach “Boston” data from MASS library in R. Select median value of owneroccupied homes, as the response and per capita crime rate, nitrogen oxides concentration, proportion of blacks and percentage of lower status of the population as predictors. The objective is to fit a multiple linear regression model of the response on the predictors. With reference to this problem, detect outliers, leverage points and influential points if any.

```
df3 = Boston
df3_subset = df3[, c("medv", "crim", "nox", "black", "lstat")]
head(df3_subset)

##   medv    crim    nox  black lstat
## 1 24.0 0.00632 0.538 396.90  4.98
## 2 21.6 0.02731 0.469 396.90  9.14
## 3 34.7 0.02729 0.469 392.83  4.03
## 4 33.4 0.03237 0.458 394.63  2.94
## 5 36.2 0.06905 0.458 396.90  5.33
## 6 28.7 0.02985 0.458 394.12  5.21
```

```

boston_model = lm(medv ~ crim + nox + black + lstat, data = df3_subset)
summary(boston_model)

```

Plot :

```
plot(cooks_d, type = "h", main = "Cook's Distance", ylab = "Cook's D")

abline(h = threshold_cook, col = "red", lty = 2)
```

Cook's Distance

Comment : The Cook's distance plot indicates the presence of a few influential observations, with one observation having particularly high influence. Most observations have negligible influence. The highly influential points may substantially affect the regression coefficients and should be examined further.

Effect of Removing Influential Points :

```
model_reduced = lm(medv ~ crim + nox + black + lstat, data = Boston[-influential_points, ])

summary(model_reduced)

## F-statistic: 151 on 4 and 489 DF,  p-value: < 2.2e-16
```

Comparison to original model : After removing influential observations, the regression coefficients and overall model fit remain broadly similar. Although some minor changes in magnitude and significance occur, the general conclusions remain unchanged. Therefore, the regression model is reasonably robust to influential observations.
